## Riverboat Simulation

## Purpose:

The purpose of this activity is to analyze the relationship between the two vector components of motion for a river boat as it travels across a river in the presence of a current.

## Procedure and Questions:

1. Navigate to the Riverboat Simulator page (Shockwave Physics Studios section) and experiment with the on-screen buttons in order to gain familiarity with the control of the animation. The width of the river, speed of the river, speed of the boat, and direction (or heading) of the boat can be modified. The animation can be started, paused, continued, single-stepped or rewound.
After gaining familiarity with the program, use it to answer the following questions:
2. Will a change in the speed of a river change the time required for a boat to cross a 100 m wide river? $\qquad$ In the space below, display some collected data which clearly support your answer. Discuss how your data provide support for your answer.
3. For a constant river width and boat heading, what variable(s) effects the time required to cross a 100 m wide river? $\qquad$ In the space below, display some collected data which support your answer. Discuss how your data provide support for your answer.
4. Suppose that a motor boat can provide a maximum speed of $10 \mathrm{~m} / \mathrm{s}$ with respect to the water. What heading will minimize the time for that boat to cross a $100-\mathrm{m}$ wide river? $\qquad$ In the space below, display some collected data which clearly support your answer. If necessary, discuss how your data provide support for your answer.

## Vectors and Projectiles

Observe that if a boat travels across a river in the presence of a current, the path changes. The current only carries the boat downstream. The current does not change the time required for the boat to traverse the river. As the boat heads across the river in the presence of the current, it is constantly heading directly towards the shore. It is not the steering of the boat which changes its direction. Rather, it is the current which is carrying it downstream. See diagram below.

5. Run the simulation with the following combinations of boat speeds and river speeds with a heading of 0 degrees (due East). Before running each simulation, perform quick calculations to determine the time required for the boat to reach the opposite bank (of a 100-meter wide river) and the distance that the boat will be carried downstream by the current. Use the simulation to check your answer(s).

| Boat Speed <br> $(\mathbf{m} / \mathbf{s})$ | River Speed <br> $(\mathbf{m} / \mathbf{s})$ | Time to Cross River <br> (s) | Distance <br> Downstream <br> (m) |
| :---: | :---: | :---: | :---: |
| 12 | 2 |  |  |
| 12 | 3 |  |  |
| 12 | 4 |  |  |
| 20 | 2 |  |  |
| 20 | 5 |  |  |

6. Study the results of your calculations in the table above and answer the following two questions. a. What feature in the table above is capable of changing the time required for the boat to reach the opposite bank of a 100-meter wide river? Explain.
b. What two quantities are needed to calculate the distance the boat travels downstream?
7. Use what you have learned from the distance-speed-time relationships to solve the following two problems.
A waterfall is located 45.0 m downstream from where the boat is launched. If the river speed is 3 $\mathrm{m} / \mathrm{s}$, then what minimum boat speed is required to cross the 100-meter wide river before falling over the falls? Show your calculations and then check your prediction using the simulation. PSYW

Repeat the above calculations to determine the boat speed required to cross the 100 -meter wide river in time if the current speed was $5 \mathrm{~m} / \mathrm{s}$ and the waterfall was located 45.0 m downstream. Again, check your predictions using the simulation. PSYW

For Questions 8 and 9: Consider a boat which begins at point A and heads straight across a 100-meter wide river with a speed of $8 \mathrm{~m} / \mathrm{s}$ (relative to the water). The river water flows south at a speed of 3 $\mathrm{m} / \mathrm{s}$ (relative to the shore). The boat reaches the opposite shore at point C.

8. Which of the following would cause the boat to reach the opposite shore in MORE time? List all that apply in alphabetical order with no spaces between letters.
a. The river is 80 meters wide.
b. The river is 120 meters wide.
c. The boat heads across the river at $6 \mathrm{~m} / \mathrm{s}$.
d. The boat heads across the river at $10 \mathrm{~m} / \mathrm{s}$.
$e$. The river flows south at $2 \mathrm{~m} / \mathrm{s}$.
f. The river flows south at $4 \mathrm{~m} / \mathrm{s}$.
g. Nonsense! None of these effect the time to cross the river.
9. Which of the following would cause the boat to reach the opposite shore at a location SOUTH of

C? List all that apply in alphabetical order with no spaces between letters.
a. The boat heads across the river at $6 \mathrm{~m} / \mathrm{s}$.
b. The boat heads across the river at $10 \mathrm{~m} / \mathrm{s}$.
c. The river flows south at $2 \mathrm{~m} / \mathrm{s}$.
d. The river flows south at $4 \mathrm{~m} / \mathrm{s}$.
e. Nonsense! None of these effect the location where the boat lands.

## Vectors and Projectiles

10. Observe that the resultant velocity $(\mathrm{v})$ is the vector sum of the boat velocity $\left(\mathrm{v}_{\mathrm{X}}\right)$ and the river velocity $\left(\mathrm{v}_{\mathrm{y}}\right)$. Use the principles of vector addition to determine the resultant velocity for each combination of boat/ current velocities listed below. Use a sketch of the two vectors and the resultant accompanied by the use of the Pythagorean theorem and trigonometric functions to determine the magnitude and direction of the resultant. PSYW

$$
\begin{aligned}
& \text { Boat Velocity }=15 \mathrm{~m} / \mathrm{s} \text {, East } \\
& \text { River Velocity }=4 \mathrm{~m} / \mathrm{s} \text {, North } \\
& \mathrm{d}_{\text {across }}=190 \mathrm{~m}
\end{aligned}
$$

Boat Velocity $=20 \mathrm{~m} / \mathrm{s}$, East
River Velocity $=5 \mathrm{~m} / \mathrm{s}$, North
$\mathrm{d}_{\mathrm{across}}=190 \mathrm{~m}$

| vresultant: |  |  |  |
| :--- | :--- | :---: | :---: |
| Magnitude: $\quad$ Magnitude: $\quad$ vresultant: |  |  |  |
| Direction: |  |  |  |

For the two sets of boat and current velocities listed above, use the Pythagorean theorem to calculate the resultant displacement of the boat in order to cross the 190-meter wide river. Show your calculations for each case in the space below.

| Boat Velocity $=15 \mathrm{~m} / \mathrm{s}$, East <br> River Velocity $=4 \mathrm{~m} / \mathrm{s}$, North | Boat Velocity $=20 \mathrm{~m} / \mathrm{s}$, East <br> River Velocity $=5 \mathrm{~m} / \mathrm{s}$, North |
| :--- | :--- |
| $\mathrm{d}_{\text {across }}=190 \mathrm{~m}$ | dacross $=190 \mathrm{~m}$ |
| $\mathrm{~d}_{\text {downstream }}=$ | $d_{\text {downstream }}=$ |
| $\mathrm{d}_{\text {resultant }}=\ldots$ | $d_{\text {resultant }}=$ |

## Summary Statement:

It is often said that "perpendicular components of motion are independent of each other." Explain the meaning of this statement and apply it to the motion of a river boat in the presence of a current.
